

During this project the only outside resource I used was stack overflow to learn how to delete columns and rows from data frame. I found that the `get_total_value` function was the most difficult to write. I tried to get around using a loop for that function and instead created a new column that compiled the sums of each individual row. The column was then deleted right after, so it didn't appear in the data frame. I also had some trouble on the `get_stock_info` function and I don't know if there was a more efficient way of implementing it. I used `.loc` to find each value and then just put three of those inside of a list. Overall, I thought this project was a good mix of topics from previous units and the pdf file refreshed my memory as to what exactly was supposed to happen in each function.
